

AERATE for a Healthy Lawn

Lawn core aeration is the process of removing small cores (plugs) of soil and thatch from the lawn to **improve the overall health of the lawn** in the following ways:

- Core aeration **improves air circulation** to and from the root

system, resulting in stronger root development.

- Enhances water and nutrient uptake**, resulting in improved fertilizer uptake and reduction in water run-off.

- Promotes thatch breakdown**

and **improves stress resistance** to excessive heat or drought.

- Reduces soil compaction** improving resiliency and cushioning.

- Especially important when **necrotic ring spot is present in the lawn**. Spring and Fall aerations will reduce compaction, thus helping to contain the spread of the disease.
